#### 4 Control of multiscale dynamics

### General formulation of the problem

We consider a system composed of a large number of interacting agents for which a microscopic and a MACROscopic description are available.

Microscopic level

$$dX^k = v_m[X]dt + N \, dB_t^k, \qquad k = 1, \ldots, N_p,$$

where  $X = (X^1, ..., X^{N_p})$ .

#### Macroscopic level

$$\partial_t 
ho(t,x) + 
abla \cdot \left( 
ho(t,x) v_{\mathcal{M}}[
ho(t,\cdot)] 
ight) = D igtarrow 
ho(t,x), \qquad t>0, \; x\in \mathbb{R}^d$$

ho(t,x) v_{\mathcal{M}}[
ho(t,\cdot)] 
ight) = D igtarrow 
ho(t,x), \qquad t>0, \,\, x \in \mathbb{R}^d$$

#### Goal

Coupling the models to improve the single-scale descriptions.

E. Cristiani (IAC-CNR)

Modeling and control of self-organizing syster

June 19-23, 2017 4 / 42

### Multiscale abstract approach: advection

The states of the system  $\{X^k\}$  and  $\rho$  are kept separate, while the coupling acts on the velocity field only.

$$\dot{X}^{k} = \mathbf{v}_{\mathbf{m}}[X], \ k = 1, \dots, N_{\mathbf{p}}, \qquad \mathbf{v}_{\mathbf{m}}[X(t)](X^{k}) = \sum_{X^{h} \in \mathcal{S}(X^{k})} \mathcal{K}(X^{k}; X^{h})$$

$$\partial_t \rho + \nabla \cdot (\rho v_M[\rho]) = 0, \qquad v_M[\rho(t, \cdot)](x) = \int_{\mathcal{S}(x)} K(x; y) \rho(t, y) dy$$

### Multiscale abstract approach: advection

The states of the system  $\{X^k\}$  and  $\rho$  are kept separate, while the coupling acts on the velocity field only.

$$\dot{X}^{k} = \mathbf{v}_{\mathbf{m}}[X], \ k = 1, \dots, N_{\mathbf{p}}, \qquad \mathbf{v}_{\mathbf{m}}[X(t)](X^{k}) = \sum_{X^{h} \in \mathcal{S}(X^{k})} \mathcal{K}(X^{k}; X^{h})$$

$$\partial_t \rho + \nabla \cdot (\rho v_M[\rho]) = 0, \qquad v_M[\rho(t, \cdot)](x) = \int_{\mathcal{S}(x)} \mathcal{K}(x; y) \rho(t, y) dy$$

New blended velocity field

$$v_{mM}[X,\rho](t,x) = \theta v_m[X(t)](x) + (1-\theta) \Lambda v_M[\rho(t,\cdot)](x), \quad \theta \in [0,1]$$

E. Cristiani (IAC-CNR)

### Multiscale abstract approach: advection

For abstract measure lovers... There is also a

Measure-based approach  

$$\frac{\partial \mu_t}{\partial t} + \nabla \cdot (\mu_t \ v[\mu_t]) = 0$$

$$\mu_t = \theta \sum_{k=1}^N \delta_{\mathbf{X}^k(t)} + (1 - \theta) \Lambda \rho(\cdot, t) \mathcal{L}^d, \quad \theta \in [0, 1]$$

E. Cristiani (IAC-CNR)

Modeling and control of self-organizing syster

(3)

### Multiscale abstract approach: diffusion

Microscopic model: Brownian motion

$$\begin{cases} dX_t^k = \sqrt{2D} dB_t^k \\ X_0^k = 0 \end{cases} \quad k = 1, \dots, N_p$$

#### Macroscopic model: heat equation

$$\left\{ egin{array}{ll} \partial_t u - \mathcal{D} \partial_x^2 u = 0, & t > 0, \; x \in \mathbb{R} \ u(0,\,x) = \delta_0, & x \in \mathbb{R}, \end{array} 
ight.$$

The correspondence

$$\mathbb{P}(X_t^k \in A) = \int_A u(t,x) \, dx, \quad \forall A \subseteq \mathbb{R}, \ \forall k.$$

E. Cristiani (IAC-CNR)

### Multiscale abstract approach: diffusion

#### Vm

The microscopic velocity field  $v_m$  should be defined as the (formal) derivative of the standard Brownian motion which is a (not rigorously defined) process with zero mean and infinite variance.

#### VM

The heat equation can be formally written as

$$\partial_t u + \partial_x (u v_M) = 0$$

with

$$v_M(t,x) := -D\frac{\partial_x u(t,x)}{u(t,x)} = \frac{x}{2t}$$

E. Cristiani (IAC-CNR)

□ ▶ ▲ □ ▶ ▲ □

### Multiscale abstract approach: diffusion

The Ito processes satisfying the SDE can be approximated by using the **strongly-consistent Euler scheme** 

$$X_{n+1}^k = X_n^k + \sqrt{2D}\Delta B_n^k, \qquad \Delta B_n^k \sim \mathcal{N}(0, \Delta t), \quad \forall n, k.$$

The right scale interpolation in this case is

Regularized Brownian motion

$$X_{n+1}^k = \left\{ egin{array}{ll} X_n^k + \sqrt{2D}\Delta B_n^k, & {
m with \ probability \ } heta, \ X_n^k + rac{X_n^k}{2t_n}\Delta t, & {
m with \ probability \ } (1- heta). \end{array} 
ight.$$

The corresponding probability density function of the particles' positions  $\{X_n^k\}_k$  tends to the function  $x \to u(t_n, x)$  as  $N_p \to \infty$  for any  $\theta \in [0, 1]$ .

### A nonlocal model

Velocity field

$$\mathbf{v}(t, \mathbf{x}) := \mathbf{v}[\mu_t](\mathbf{x}) = \mathbf{v}_{\mathsf{des}}(\mathbf{x}) + \mathbf{v}_{\mathsf{int}}[\mu_t](\mathbf{x}),$$

#### Desired velocity

 $v_{des} : \mathbb{R}^2 \to \mathbb{R}^2$  the velocity that pedestrians would set to reach their destination (considering obstacles) if they were alone in the domain.

Interaction velocity

$$\begin{aligned} \mathbf{V}_{\mathsf{int}}[\mu_t](x) &= \int_{\mathcal{S}(x)} \mathcal{F}(|y-x|) \frac{y-x}{|y-x|} \, d\mu_t(y), \\ \mathcal{F}(s) &= -\frac{F_r}{s} \chi_{[0,\,R_r]}(s) \qquad (\mathsf{repulsion effect}) \end{aligned}$$

### A model with opinion polls

An opinion is described by a continuous variable  $w(t) \in [-1, 1]$  varying in time due to the interactions with others people. If we consider political opinions, the sign of the opinion sgn(w) expresses the voting intent (1 stands for "yes" or "left", -1 stands for "no" or "right"), while the norm |w| gives the degree of conviction.

Microscopic model

$$dw_{k} = (1 - |w_{k}|^{\delta}) \left( \overbrace{C_{\text{int}} \frac{1}{N_{p}} \sum_{h=1}^{N_{p}} (w_{h} - w_{k}) dt}^{\text{interactions}} + \overbrace{\sqrt{2}C_{\text{noise}} dB_{t}^{k}}^{\text{self-thinking}} \right)$$

into vo otio no

for  $k=1,..,N_p, \ t\in [0,T]$ , where

- $(1-|w_k|^{\delta})$  is the propensity to change opinion;
- $B_t^k$  are independent Brownian motions.

### Introducing the break of symmetry by opinion polls

$$P^+ := rac{ ext{card}\{k: w_k(T_{ ext{poll}}) > W^0\}}{N_p}, \quad P^- := rac{ ext{card}\{k: w_k(T_{ ext{poll}}) < -W^0\}}{N_p}$$

where  $W^0 \in [0, 1)$  is a "null threshold" such that if  $|w_k| \le W^0$  then the *k*th individual is regarded as indecisive.

Result of the poll

$$P := P^+ - P^- \in [-1, 1],$$

イロン イヨン イヨン イヨン

### The macroscopic model

Define the probability density function  $\rho = \rho(t, w)$  in such a way that  $\rho(t, w)dw$  is the probability that at time t a generic individual has an opinion in [w, w + dw]. We get that  $\rho$  is the solution to

#### The Fokker-Planck equation

$$\partial_t \rho + \partial_w (\mathcal{K}_{\mathsf{adv}}[\rho]\rho) = \partial_w^2 (C_{\mathsf{noise}}^2 (1 - |w|^\delta)^2 \rho),$$

where

$$\mathcal{K}_{\mathsf{adv}}[\rho(t,\cdot)](w) = (1 - |w|^{\delta}) \left( \mathcal{C}_{\mathsf{int}} \int_{-1}^{1} (w' - w)\rho(t,w')dw' + \underbrace{\mathcal{C}_{\mathsf{poll}}b(t,P,w)}_{\mathsf{from micro model}} \right)$$
